(Received 30 September 1986; accepted 3 June 1987)

The detailed influence of an untrapped-electron population on the sideband instability in a helical wiggler free electron laser is investigated for small-amplitude perturbations about a constant-amplitude ($\hat{\phi}_0 = \text{const}$) primary electromagnetic wave with slowly varying equilibrium phase $\phi_0^0$. A simple model is adopted in which all of the trapped electrons are deeply trapped, and the equilibrium motion of the untrapped electrons (assumed monoenergetic) is only weakly modulated by the ponderomotive potential. The theoretical model is based on the single-particle orbit equations together with Maxwell's equations and appropriate statistical averages. Moreover, the stability analysis is carried out in the ponderomotive frame, which leads to a substantial simplification in deriving the dispersion relation. Detailed stability properties are investigated over a wide range of dimensionless pump strength $\Omega_b/\Gamma_bck_0$ and fraction of untrapped electrons $f_u = \hat{n}_u/\hat{n}_b$. When both trapped and untrapped electrons are present, there are generally two types of unstable modes, referred to as the sideband mode, and the untrapped-electron mode. For $f_u = 0$, only the sideband instability is present. As $f_u$ is increased, the growth rate of the sideband instability decreases, whereas the growth rate of the untrapped-electron mode increases until only the untrapped-electron mode is unstable for $f_u = 1$. It is found that the characteristic maximum growth rate of the most unstable mode varies by only a small amount over the entire range of $f_u$ from $f_u = 0$ (no untrapped electrons) to $f_u = 1$ (no trapped electrons). The present analysis suggests that the linear and nonlinear evolution of the beam electrons and radiation field may be substantially modified by the presence of an untrapped-electron component when $f_u \gtrsim 0.2$.

I. INTRODUCTION

Free electron lasers (FEL's),1-4 as evidenced by the growing experimental5-22 and theoretical23-27 literature on this subject, can be effective sources for coherent radiation generation by intense relativistic electron beams. Recent theoretical studies have included investigations of nonlinear effects23-28 and saturation mechanisms, the influence of finite geometry on linear stability properties,48-53 novel magnetic field geometries for radiation generation,48,54-58 and fundamental studies of stability behavior.59-60 One topic of considerable practical interest is the sideband instability26 which results from the bounce motion of electrons trapped in the (finite-amplitude) ponderomotive potential. Both kinetic23-25 and single-particle36-47 models of the sideband instability have been developed, and numerical simulations39-47 have been carried out. However, with the exception of the recent kinetic formalism developed by Davidson et al.,23-25 the analytical treatments have consistently neglected the effects of any untrapped-electron population.

The purpose of the present analysis is to investigate the detailed influence of untrapped electrons on the sideband instability. Small-amplitude perturbations are assumed about a constant-amplitude ($\hat{\phi}_0 = \text{const}$) primary electromagnetic wave with slowly varying equilibrium phase $\phi_0^0$. Moreover, we adopt a simple model in which all of the trapped electrons are deeply trapped, and the equilibrium motion of the untrapped electrons (assumed monoenergetic) is only weakly modulated by the ponderomotive potential. The theoretical model (Sec. II) is based on the single-particle orbit equations together with Maxwell's equations and appropriate statistical averages.36,37 Like our recent treatment37 of the sideband instability (which neglects the effects of untrapped electrons), the present analysis is carried out in the ponderomotive frame, which leads to a substantial simplification in the analysis.

The theoretical model and assumptions are described in Sec. II. A tenuous, relativistic electron beam propagates through a constant-amplitude helical wiggler magnetic field with wavelength $\lambda_0 = 2\pi/k_0 = \text{const}$, and normalized amplitude $a_0 = e\bar{B}_0/mc^2k_0 = \text{const}$ [Eq. (1)]. The model neglects longitudinal perturbations (Compton-regime approximation with $\delta\phi = 0$) and transverse spatial variations ($\partial/\partial x = 0 = \partial/\partial y$). Moreover, the analysis is carried out for the case of finite-amplitude primary electromagnetic wave ($\omega_0, k_0$) with right-circular polarization and slowly varying normalized amplitude $\delta_0(z,t)$ and wave phase $\delta_0(z,t)$ in the Eikonal approximation [Eq. (2)]. A detailed investigation of the sideband instability simplifies considerably if the analysis is carried out in the ponderomotive frame37,71,72 moving with velocity $v_p = \omega_0/(k_0 + \lambda_0)$. In the

---

a)Permanent address: Plasma Fusion Center, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139.
ponderomotive frame ("primed" variables), the nonlinear evolution of \( \hat{a}_z(z',t') \) and \( \delta \gamma(z',t') \) is described by Eqs. (5) and (6), and the electron orbits evolve according to Eq. (13).

In Sec. III, the influence of untrapped electrons on the sideband instability is investigated for small-amplitude perturbations about a primary electromagnetic wave with constant amplitude \( \hat{a}_z^0 = \text{const} \) (independent of \( z' \) and \( t' \)). The trapped and untrapped electrons are treated as distinct components. Moreover, the principal assumptions in the present analysis are the following (Sec. III A).

(a) All of the trapped electrons are deeply trapped with a sharply defined energy \( \gamma_\text{tr} = \gamma_0 \approx \gamma_\text{tr} \) \[= \left[ 1 + (a_0 - \hat{a}_z^0)^2 \right]^{1/2} \]. This implies that the trapped electrons are spatially localized ("bunched") near the bottom of the ponderomotive potential (Fig. 2). The average density of the trapped electrons in the ponderomotive frame is \( \hat{h}_\text{tr} = \hat{h}_0 / \gamma_\text{tr} \).

(b) All of the untrapped electrons have a sharply defined energy \( \gamma'_u = \gamma'_0 > \gamma'_+ = \left[ 1 + (a_0 + \hat{a}_z^0)^2 \right]^{1/2} \), where \( \gamma'_0 \) is sufficiently large that the motion of the untrapped electrons is only weakly modulated by the ponderomotive potential (Fig. 2). The average density of the untrapped electrons in the ponderomotive frame is \( \hat{h}'_u = \hat{h}_u / \gamma'_0 \).

(c) Consistent with (a) and (b), we assume that the perturbations are about a quasisteady equilibrium state characterized by \( \hat{a}_z^0 = \text{const} \) (independent of \( z' \) and \( t' \)) and \( \partial \hat{a}_z^0 / \partial t' = 0 \). However, a slow spatial variation of the equilibrium phase \( \hat{a}_z^0 \) is required (Eq. (41)).

Following a discussion of the quasisteady equilibrium state (Sec. III B), we analyze the linearized wave and particle orbit equations (Sec. III C), and derive the dispersion relation (70) for small-amplitude perturbations in the ponderomotive frame (Sec. III D). Here, it is assumed that the perturbed amplitude \( \hat{a}_r(z',t') \), the perturbed phase \( \delta \gamma(z',t') \), etc., vary as \( \exp [- i (\Delta \omega') t' + i (\Delta \kappa') z'] \), where \( \text{Im} (\Delta \omega') > 0 \) corresponds to instability (temporal growth). The dispersion relation (70) relates \( \Delta \omega' \) to \( \Delta \kappa' \) and other system parameters such as \( \delta \gamma', \kappa', \hat{h}_r, \hat{h}'_u \), etc.

Finally, in Sec. IV, the dispersion relation (70) is used to investigate detailed properties of the sideband instability including the effects of the untrapped electrons. First, we transform Eq. (70) back to the laboratory-frame frequency \( \omega = \omega_0 + \Delta \omega \) and wavenumber \( k = k_0 + \Delta k \) making use of the transformation in Eq. (71) relating \( (\Delta \omega, \Delta k) \) to \( (\Delta \omega', \Delta \kappa') \). After some algebraic manipulation (Sec. IV A), we find that the dispersion relation (70) can be expressed as Eq. (80) in the laboratory frame. Equation (86), which is equivalent to Eq. (80), constitutes the final dispersion relation in dimensionless variables analyzed numerically in Sec. IV B. We introduce the parameter \( f_u = \hat{h}_u / \hat{h}_0 \), where \( \hat{h}_u = \hat{h}_r + \hat{h}_s \) is the total average beam density in the laboratory frame (Eq. (82)). For \( f_u = 0 \), which corresponds to no untrapped electrons \( \hat{h}_u = 0 \), Eq. (86) is the familiar dispersion relation for the sideband instability\(^{37,71,72} \) in circumstances where the equilibrium wave phase is slowly varying [Eq. (41)]. For \( f_u \neq 0 \), however, it is found that the untrapped electrons can significantly modify stability behavior (Sec. IV B). Detailed stability properties are investigated over a wide range of both the dimensionless pump strength and the fraction of untrapped electrons. When both trapped and untrapped electrons are present, there are generally two types of unstable modes, referred to as the sideband mode, and the untrapped-electron mode. For \( f_u = 0 \), only the sideband instability is present. As \( f_u \) is increased, the growth rate of the untrapped-electron mode increases until only the untrapped-electron mode is unstable for \( f_u = 1 \). While the limiting values, \( f_u = 0 \) and \( f_u = 1 \), are both unlikely to be achieved experimentally, their inclusion in the present analysis serves two purposes. First, it allows the dispersion relation (86) to be checked in the two limiting cases where stability properties have previously been calculated. Second, it allows us to identify clearly the untrapped-electron mode (\( f_u = 1 \)) and the sideband mode (\( f_u = 0 \)), and thereby calibrate stability properties for the case where both modes are present (\( f_u \neq 0 \) and \( f_u \neq 1 \)) and synergistic effects are important.

The present analysis indicates that the detailed stability properties are quite different for the two unstable modes. Equally important, however, it is found that the characteristic maximum growth rate of the most unstable mode varies by only a small amount over the entire range of \( f_u \) from \( f_u = 0 \) (no untrapped electrons) to \( f_u = 1 \) (no trapped electrons).

II. THEORETICAL MODEL AND ASSUMPTIONS

A. Basic equations and assumptions

A tenuous, relativistic electron beam propagates in the \( z \) direction through a constant-amplitude helical wiggle magnetic field with wavelength \( \lambda_0 = 2 \pi / k_0 = \text{const} \), normalized amplitude \( a_w = e \hat{B}_w / mc k_0 = \text{const} \), and vector potential specified by

\[
A_w(x) = - (mc^2/e) a_w (\cos k z \mathbf{e}_x + \sin k z \mathbf{e}_y).
\]

The model neglects longitudinal perturbations (Compton-regime approximation, \( \delta k \approx 0 \)) and transverse spatial variations (\( \partial / \partial z = \partial / \partial y \)). Moreover, the analysis is carried out for the case of a finite-amplitude primary electromagnetic wave (\( \omega_0, k_0 \)) with right-circular polarization and vector potential specified by

\[
A_s(x,t) = \left( mc^2/e \right) \hat{a}_s(x,t) \left\{ \cos \left( k z - \omega_0 t + \delta_s(z,t) \right) \mathbf{e}_x \right. \\
\left. - \sin \left( k z - \omega_0 t + \delta_s(z,t) \right) \mathbf{e}_y \right\},
\]

where the normalized amplitude \( \delta_s(z,t) \) and wave phase \( \delta_s(z,t) \) are treated as slowly varying (Eikonal approximation). Here, \( - e \) is the electron charge, \( m \) is the electron rest mass, and \( c \) is the speed of light in vacuo. In Eqs. (1) and (2), the wiggle magnetic field is determined from \( B_w = \nabla \times A_w \), and the electromagnetic wave field is determined from \( \mathbf{B} = \nabla \times \mathbf{A}_s \) and \( \mathbf{E}_s = - c^{-1} \partial \mathbf{A}_s / \partial t \). A detailed investigation of the sideband instability simplifies considerably if the analysis is carried out in the ponderomotive frame moving with velocity \( \mathbf{v}_p = \omega_0 / (k_0 + \kappa_0) \).

In the ponderomotive frame, it is found\(^{37} \) that the transformed energy \( \gamma'_0(t') \) is approximately constant, with \( d \gamma'_0 / d t' \approx 0 \) in the Eikonal approximation [Eqs. (9) and

The simplification considerably the analytical treatment of the electron orbits in the combined helical wiggler field and the finite-amplitude primary electromagnetic wave. Therefore, the present analysis is carried out in ponderomotive-frame variables \((z', t', \gamma')\) defined by the Lorentz transformation
\[
\begin{align*}
    z' &= \gamma_p (z - v_p t), \\
    t' &= \gamma_p (t - v_p z/c^2), \\
    \gamma' &= \gamma_p (1 - v_p^2/c^2)^{-1/2},
\end{align*}
\]
where \(\gamma_p = (1 - v_p^2/c^2)^{-1/2}\), \(\gamma_p = (m^2 c^4 + c^2 p_{z'}^2 + c^2 p_{t'}^2)^{1/2}\) is the mechanical energy, and the components of momentum \((p_{z'}', p_{t'}', p_v')\) are related to the velocity \(v' = dx'/dt' + by' = \gamma' v\).

In the ponderomotive frame, the slow nonlinear evolution of \(\hat{a}_j (z', t')\) and \(\delta_j (z', t')\) is described by
\[
\begin{align*}
    2\omega'_j \left( \frac{\partial}{\partial t'} + \frac{k_j^2}{\omega'_j} \frac{\partial}{\partial z'} \right) \hat{a}_j &= 4\pi e^2 a_w m L' \left( \sum_{j} \frac{\sin(\theta_j + \delta'_j)}{\gamma_j'} \right), \\
    2\omega'_j \hat{a}_j \left( \frac{\partial}{\partial t'} + \frac{k_j^2}{\omega'_j} \frac{\partial}{\partial z'} \right) \delta_j &= 4\pi e^2 a_w m L' \left( \sum_{j} \frac{\cos(\theta_j + \delta'_j)}{\gamma_j'} \right),
\end{align*}
\]
where the real oscillation frequency \(\omega'_j\) and wavenumber \(k_j\) are related by the dispersion relation
\[
\omega_j^2 = c^2 k_j^2 + 4\pi e^2 a_w m L' \left( \sum_{j} \frac{1}{\gamma_j'} \right).
\]

In Eqs. (5)–(7), \(\Sigma_j\) denotes a statistical average, and the axial orbit \(\theta_j (t') = k_j z_j (t')\) and energy \(\gamma_j (t')\) of the \(j\) th electron are solved
\[
\begin{align*}
    \frac{d^2}{dt'^2} \theta_j + \frac{c^2 k_j^2 a_w}{\gamma_j^2} \Im \left[ \hat{a}_j \exp(it \theta_j + iz_j') \right] &= \frac{c^2 k_j^2 a_w}{\gamma_j^2} \Re \left[ \exp(it \theta_j) \left( \frac{\partial}{\partial t'} + \frac{1}{c^2} \frac{dz_j'}{dt'} \frac{\partial}{\partial t'} \right) \right. \\
    &\left. \times \left[ \hat{a}_j \exp(it \delta_j') \right] \right],
\end{align*}
\]
\[
\begin{align*}
    \frac{d}{dt'} \gamma_j &= - \frac{a_w}{\gamma_j} \Re \left( \frac{\partial}{\partial t'} \left[ \hat{a}_j \exp(it \delta_j') \right] \right).
\end{align*}
\]

In Eqs. (8) and (9), \(k_j\) is the wavenumber of the ponderomotive potential, and \(\gamma_j\) is defined by
\[
\gamma_j^2 = 1 + \left( \frac{p_{z'}^2}{m c^2} \right) + a_w^2 + \delta_j^2 + 2a_w \Re [\hat{a}_j \exp(it \delta_j')]
\]
in the ponderomotive frame. In obtaining Eqs. (8) and (9) from \(dp_{\gamma_j}/dt' = -m c^2 \gamma_j \partial \gamma_j / \partial t'\) and \(\gamma_j / dt' = \gamma_j / \partial t'\), we have neglected \(\delta_j^2 \ll 1 + a_w^2\) in Eq. (10). Moreover, it is assumed that all electrons have zero transverse canonical momentum, i.e., \(P_{\gamma_j} = 0 = P_{\delta_j}\).

There is some latitude in specifying the precise operational meaning of the statistical averages \(\Sigma_j\) occurring in Eqs. (5)–(7). For present purposes, let us assume that the orbits \(z_j (t')\) and \(\gamma_j (t')\) have been calculated from Eqs. (8) and (9) in terms of the initial values \(z_j (0)\) and \(\gamma_j (0)\). Then the simplest definition of the statistical average \(\Sigma_j\) over some phase function \(\psi (\theta_j, \gamma_j)\) is given by
\[
\begin{align*}
    \frac{1}{L'} \int_{\gamma_j} \int_{\theta_j} \psi (\theta_j, \gamma_j) d\gamma_j d\theta_j &= \int_{\gamma_j} \int_{\theta_j} \int_{0}^{2\pi} \frac{d\theta_j}{2\pi} \frac{d\gamma_j}{2\pi} G(\theta_j, \gamma_j) \psi (\theta_j, \gamma_j) \int_{0}^{2\pi} \frac{d\gamma_j}{2\pi} G(\theta_j, \gamma_j) \psi (\theta_j, \gamma_j).
\end{align*}
\]
Here, \(\bar{N}\) is the average density of the beam electrons in the ponderomotive frame, and \(G(\theta_j, \gamma_j)\) is the (probability) distribution of electrons in initial phase \(\theta_j\) and energy \(\gamma_j\). Moreover, \(L' = 2\pi / k_j\) is the basic periodicity length in the ponderomotive frame.

Equations (5)–(9) constitute a closed description of the nonlinear evolution of the system. In this regard, further simplification of Eqs. (8) and (9) is possible by virtue of the assumption of slowly varying wave amplitude and phase (Eikonal approximation), i.e.,
\[
\begin{align*}
    |\omega'_j| &\gg \left| \left[ \hat{a}_j \exp(it \delta_j') \right] ^{-1} \frac{\partial}{\partial t'} \left[ \hat{a}_j \exp(it \delta_j') \right] \right|, \\
    |k'_j| &\gg \left| \left[ \hat{a}_j \exp(it \delta_j') \right] ^{-1} \frac{\partial}{\partial t'} \left[ \hat{a}_j \exp(it \delta_j') \right] \right|.
\end{align*}
\]
In particular, to lowest order, it is valid to neglect the local temporal and spatial derivatives on the right-hand sides of Eqs. (8) and (9). This gives the approximate dynamical equations
\[
\begin{align*}
    \frac{d^2}{dt'^2} \theta_j + \frac{c^2 k_j^2 a_w}{\gamma_j^2} \Im \left[ \hat{a}_j \exp(it \theta_j + iz_j') \right] &= 0, \\
    \frac{d}{dt'} \gamma_j &= 0.
\end{align*}
\]

The major benefit of carrying out the analysis in the ponderomotive frame is evident from Eqs. (13) and (14). To lowest order, the particle energy \(\gamma_j\) can be treated as constant in Eqs. (5)–(7) and (13).

In the subsequent analysis, we make use of the closed description of the nonlinear evolution of the system provided by Eqs. (5)–(7) and Eqs. (13) and (14).

### B. Definitions and notation

For future reference, in this section we establish the basic definitions and notation to be used in the stability analysis in Secs. III and IV.

The wave frequency and wavenumber \((\omega', k')\) in the ponderomotive frame are related to the wave frequency and wavenumber \((\omega, k)\) in the laboratory frame by
\[
\begin{align*}
    \omega &= \gamma_p (\omega - k v_p), \\
    k' &= \gamma_p (k - \omega v_p / c^2),
\end{align*}
\]
where \(v_p\) is defined in Eq. (3) and \(\gamma_p = (1 - v_p^2 / c^2)^{-1/2}\). As a special case, we obtain \(\omega' = \gamma_p (\omega - k, v_p)\) from Eq. (15), which gives
\[
\begin{align*}
    \omega' &= \gamma_p k v_p.
\end{align*}
\]
In the present analysis, it is also assumed that the electron beam is sufficiently tenuous that beam dielectric effects can be neglected in the dispersion relation (7) (and its laboratory-frame analog). This gives the vacuum dispersion relation \( \omega_s^2 = c^2 k_s^2 \), or equivalently \( \omega_s^2 = c^2 k_s^2 \), for the primary electromagnetic wave. Assuming a forward-moving electromagnetic wave, we solve the simultaneous resonance conditions

\[
\omega_s = +ck_s,
\]

\[
\omega_s = (k_s + k_0)v_p,
\]

for \( \omega_s \) and \( k_s \). This readily gives the familiar results\(^{37}\)

\[
\omega_s = \frac{\gamma_p}{c}(1 + v_p/c)k_0 \mu_p,
\]

\[
k_s = \frac{\gamma_p}{c}(1 + v_p/c)(v_p/c)k_0, \tag{18}
\]

where \( v_p \) is (nearly) synchronous with the average axial velocity \( v_0 \) of the beam electrons. Moreover, from Eqs. (18), the ponderomotive wave number \( k_p' = (k_s + k_0) / \gamma_p \) can be expressed as

\[
k_p' = \frac{\gamma_p}{c}(1 + v_p/c)k_0. \tag{19}
\]

In circumstances where perturbations are about a primary electromagnetic wave with amplitude \( \delta_0 = \text{const} \) (independent of \( x' \) and \( t' \)), it is useful in analyzing the orbit equation (13) to introduce the bounce frequency \( \partial_0(\gamma_j') \) defined by\(^{23}\)

\[
\partial_0(\gamma_j') = (c^2 k_s^2 a_w \delta_0^2 / \gamma_j'^{3/2})^{1/2}. \tag{20}
\]

Here, \( a_w > 0 \) and \( \delta_0 > 0 \) are assumed without loss of generality, and \( \partial_0(\gamma_j') \) is the effective bounce frequency of deeply trapped electrons with energy \( \gamma_j' \). A detailed analysis\(^{23}\) of Eqs. (10) and (13) shows that the zero-order electron motion is untrapped for energies \( \gamma_j' \) satisfying (Figs. 1 and 2)

\[
\gamma_j' > \gamma_j^+ \equiv [1 + (a_w + \delta_0^2)^{1/2}]. \tag{21}
\]

That is, when Eq. (21) is satisfied, the particle motion is modulated by the ponderomotive potential, but the normal-velocity \( \partial_0 \hat{v}_h / \partial t' \) does not change polarity (Fig. 1). On the other hand, for \( \gamma_j' < \gamma_j^+ \), the electrons are trapped, and the zero-order motion described by Eq. (13) is cyclic, corresponding to periodic motion in the ponderomotive potential. From Eqs. (10) and (13), it is readily shown that the minimum allowable energy of a trapped electron is\(^{23}\)

\[
\gamma_j^- \equiv [1 + (a_w - \delta_0^2)^{1/2}]. \tag{22}
\]

Because \( \delta_0 \ll a_w \) in the regimes of practical interest, we note from Eqs. (21) and (22) that the characteristic energy of a trapped electron is approximately \( \gamma_j (1 + a_w^2)^{1/2} \).

The stability analysis in Secs. III and IV specializes to the case where there are two classes of electrons: untrapped electrons with energy \( \gamma_j' = \gamma_j^+ > \gamma_j^- \), and deeply trapped electrons with energy \( \gamma_j' = \gamma_j^- \). For the deeply trapped electrons, the effective bounce frequency in the laboratory frame is defined by \( \Omega \equiv \partial_0(\gamma_j^-) / \gamma_j' \), i.e.,

\[
\Omega = \left( c^2 k_s^2 a_w \delta_0^2 / \gamma_j'^{3/2} \right)^{1/2}. \tag{23}
\]

Because \( \delta_0^2 \ll a_w \), we estimate \( \gamma_j^- \approx \gamma_j^+ (1 + a_w^2)^{1/2} \) in Eq. (23), and make use of Eq. (19) to express Eq. (23) in the equivalent (and more familiar) form

\[
\Omega = \left( 1 + \frac{v_p}{c} \right) \left( \frac{a_w \delta_0^2}{1 + a_w \delta_0^2} \right)^{1/2} k_0. \tag{24}
\]

Continuing with definitions, we denote the average density of the trapped electrons in the ponderomotive frame by \( \bar{n}_T = \bar{n}_r / \gamma_j ' \), and the average density of the untrapped electrons by \( \bar{n}_u = \bar{n}_r / \gamma_j ' \). It is convenient to introduce the corresponding plasma frequencies defined by

\[
\hat{\omega}_T^2 = 4\pi n_T e^2 / m = 4\pi \bar{n}_r e^2 / \gamma_j ' m, \tag{25}
\]

\[
\hat{\omega}_u^2 = 4\pi n_u e^2 / m = 4\pi \bar{n}_r e^2 / \gamma_j ' m.
\]

A detailed investigation of Eqs. (5) and (6) (Secs. III and IV) shows that the appropriate small parameters, \( \epsilon_r \ll 1 \) and \( \epsilon_u \ll 1 \), used in analyzing the wave equations are defined by

\[
\epsilon_{\gamma'} c k_p' = a_w \hat{\omega}_T^2 / 2 \alpha c \gamma_j '-' \delta_0^2,
\]

\[
\epsilon_{\gamma'} c k_p' = a_w \hat{\omega}_u^2 / 2 \alpha c \gamma_j '-' \delta_0^2. \tag{26}
\]

Here, \( \omega_{\gamma'} \) is defined in Eq. (16), \( \gamma_j '-' \) is the energy of the untrapped electrons, and \( \gamma_j '-' \), \( \delta_0^2 \), and \( \hat{\omega}_T^2 \) are defined in Eqs. (22) and (25). Note from Eqs. (25) and (26) that both \( \epsilon_{\gamma'} \) are related by \( \epsilon_{\gamma'} = (\hat{\omega}_T / \bar{n}_r) (\gamma_j '-' \delta_0^2) \epsilon_u \). In Sec. III, we will find that \( \epsilon_u \) is related to the (slow) variation of the equilibrium wave phase \( \delta_0 \) by \( \partial \delta_0 / \partial t = \epsilon_{\gamma'} c k_p' \) [Eq. (41)].

Finally, for future reference, we introduce the small dimensionless parameter \( \Gamma_{\gamma'} \) defined by\(^{23,37}\)}

\[
\Gamma_{\gamma'} \equiv \frac{\gamma_j '-' \delta_0^2}{\gamma_j '-' \delta_0^2}.
\]
\[ \Gamma_r = \frac{1}{4} \frac{a_w}{\gamma'_r^2} \frac{\tilde{\omega}_T^2}{\gamma'_r^2 c_0^2} \left( 1 + \frac{v_p}{c} \right) \ll 1. \]  

(27)

In the absence of untrapped electrons \( \left( \hat{n}_r = 0 \right) \), the quantity \( 3^{1/2} \Gamma_r c_k c_0/2 \) can be identified with the linear gain (temporal growth rate) in the weak-pump regime \( \left( \Omega_b / \Gamma_c c_0 \ll 1 \right) \). Moreover, from Eqs. (19), (23), (26), and (27), it can be shown that \( \Gamma_r \) and \( \varepsilon T_r \) are related by

\[ \varepsilon T_r = 2 \Gamma_r \left( \Gamma_c c_k c_0 / \Omega_b \right)^2. \]  

(28)

From Eq. (28), we note that \( \varepsilon T_r \ll 1 \) necessarily requires that the zero-order wave amplitude \( \delta_0^0 \) be sufficiently large that \( \left( \Omega_b / \Gamma_c c_0 \right)^2 \gg 2 \Gamma_r \) (a small parameter).

III. STABILITY ANALYSIS FOR SMALL-AMPLITUDE PERTURBATIONS

A. Assumptions and model

We now make use of Eqs. (5), (6), and (13) with \( \gamma'_r = \gamma'_r^0 \approx \gamma'_r^0 = [1 + \left( a_{w} - \delta_0^0 \right)^2]^{1/2} \). From Eq. (13), this implies that the trapped electrons are spatially localized ("bunched") near the bottom of the ponderomotive potential with \( \theta' + \delta' \approx 2 \pi n \), where \( n = 0, \pm 1, \pm 2 \ldots \) is an integer. The average density of the trapped electrons in the ponderomotive frame is \( \hat{n}_T = \hat{n}_T / \gamma'_r \).

(a) All of the trapped electrons are deeply trapped with a sharply defined energy \( \gamma'_r = \gamma'_r^0 \approx \gamma'_r^0 - [1 + \left( a_{w} - \delta_0^0 \right)^2]^{1/2} \). From Eq. (13), this implies that the trapped electrons are spatially localized ("bunched") near the bottom of the ponderomotive potential with \( \theta' + \delta' \approx 2 \pi n \), where \( n = 0, \pm 1, \pm 2 \ldots \) is an integer. The average density of the trapped electrons in the ponderomotive frame is \( \hat{n}_T = \hat{n}_T / \gamma'_r \).

(b) All of the untrapped electrons have a sharply defined energy \( \gamma'_u = \gamma'_u^0 \approx \gamma'_u^0 - [1 + \left( a_{w} + \delta_0^0 \right)^2]^{1/2} \), where \( \gamma'_u^0 \) is sufficiently large that the motion of the untrapped electrons is only weakly modulated by the ponderomotive potential. Strictly speaking, this requires that \( \gamma'_u^0 - \gamma'_u^0 \) be large in comparison with the total well depth \( \delta_0^0 \).

(c) Consistent with (a) and (b), we assume that the perturbations are about a quasisteady equilibrium state characterized by \( \theta' = \text{const} \) (independent of \( \theta' \) and \( t' \)) and \( \partial^2 \theta' / \partial t^2 = 0 \). However, a slow spatial variation of the equilibrium phase \( \delta_0^0 \) is required [Eq. (41)].

In the subsequent analysis, we denote the axial coordinate of the (deeply) trapped electrons with energy \( \gamma'_r \approx \gamma'_r^0 \) by \( \theta' = k'_z \zeta'_r(t') \), and the axial coordinate of the untrapped electrons with energy \( \gamma'_u \) is denoted by \( \theta'_u = k'_z \zeta'_u(t') \). The corresponding bounce frequencies are defined by

\[ \omega_{BY} = \omega_{BY} \left( \gamma'_r^0 \right) = \left( c^2 k'_z a_{w} \delta_0^0 / \gamma'_r^0 \right)^{1/2}, \]

\[ \omega_{BU} = \omega_{BU} \left( \gamma'_u \right) = \left( c^2 k'_z a_{w} \delta_0^0 / \gamma'_u \right)^{1/2}, \]  

(29)

where \( \delta_0^0 = \text{const} \) is the equilibrium amplitude of the primary electromagnetic wave. Note from Eqs. (29) that \( \partial_{BY} = \left( \gamma'_r / \gamma'_r^0 \right) \omega_{BY} = \omega_{BY} \), because \( \gamma'_r^0 \) typically exceeds \( \gamma'_r \) by only a small amount for \( a_{w} \delta_0^0 \ll 1 \). Making use of assumptions (a)–(c), it readily follows from Eqs. (5), (6), and (13) that the nonlinear wave equations and the equations of motion for the trapped and untrapped electrons can be expressed as

\[ \left( \frac{\partial}{\partial t'} + \frac{c^2 k'_z \gamma'_r}{\omega_{BY}^2} \frac{\partial}{\partial z')} \right) \delta_r = \frac{a_w}{2 \omega_{BY}^2} \sin \left( \theta' + \delta'_r \right) \]

\[ + \frac{a_w}{2 \omega_{BY}^2} \sin \left( \theta' + \delta'_r \right) \]

\[ \delta_r \frac{\partial}{\partial t'} + \frac{c^2 k'_z}{\omega_{BY}^2} \frac{\partial}{\partial z'} \right) \delta'_r = \frac{a_w}{2 \omega_{BY}^2} \sin \left( \theta' + \delta'_r \right) \]

\[ + \frac{a_w}{2 \omega_{BY}^2} \sin \left( \theta' + \delta'_r \right) \]

(30)

and

\[ \frac{d^2}{dt^2} \theta' + \Delta_{\theta}^2 \frac{\partial}{\partial \theta'} \frac{\partial}{\partial \theta'} \sin \left( \theta' + \delta'_r \right) = 0, \]

(32)

\[ \frac{d^2}{dt^2} \theta' + \Delta_{\theta}^2 \frac{\partial}{\partial \theta'} \frac{\partial}{\partial \theta'} \sin \left( \theta' + \delta'_r \right) = 0. \]

(33)

In Eqs. (30) and (31), \( \Delta_{\theta}^2 \) and \( \Delta_{\theta}^2 \) are defined in Eq. (25), and the statistical average \( \langle \cdots \rangle_u \) denotes an average over initial phases of the untrapped electrons, i.e.,

\[ \langle \cdots \rangle_u \equiv \int_0^{2 \pi} \frac{d \theta'_u(0)}{2 \pi} \cdots \]

(34)

In terms of the small parameters \( \varepsilon T_r \) and \( \varepsilon T_u \) defined in Eq. (26), the nonlinear wave equations (30) and (31) can be expressed in the equivalent forms

\[ \left( \frac{\partial}{\partial t'} + \frac{c^2 k'_z}{\omega_{BY}^2} \frac{\partial}{\partial z'} \right) \delta_r = \varepsilon T_r \left( c^2 k'_z a_{w} \delta_0^0 \sin \left( \theta' + \delta'_r \right) \right) \]

\[ + \varepsilon T_r \left( c^2 k'_z a_{w} \delta_0^0 \sin \left( \theta' + \delta'_r \right) \right) \]

(35)

and

\[ \delta_r \left( \frac{\partial}{\partial t'} + \frac{c^2 k'_z}{\omega_{BY}^2} \frac{\partial}{\partial z'} \right) \delta'_r = \varepsilon T_r \left( c^2 k'_z a_{w} \delta_0^0 \cos \left( \theta' + \delta'_r \right) \right) \]

\[ + \varepsilon T_r \left( c^2 k'_z a_{w} \delta_0^0 \cos \left( \theta' + \delta'_r \right) \right). \]

(36)

The coupled equations (32), (33), (35), and (36) constitute a closed description of the nonlinear evolution of the system within the context of assumptions (a)–(c).

We now make use of Eqs. (32), (33), (35), and (36) to investigate detailed properties of the sideband instability (including the influence of both trapped and untrapped electrons) for small-amplitude perturbations about a primary electromagnetic wave with constant amplitude \( \delta_0^0 \) and slowly varying phase \( \delta_0^0 \). Each quantity is expressed as its equilibrium value plus a perturbation, i.e.,

\[ \delta_r = \delta_0^0 + \delta_0^0, \quad \delta'_r = \delta_0^0 + \delta_0^0, \quad \delta'_r = \delta_0^0 + \delta_0^0, \quad \theta' = \theta'_0 + \Delta \theta_0^0, \quad \theta'_0 = \theta'_u + \delta_0^0. \]

(37)

For the deeply trapped electrons with \( \theta' + \delta'_r \approx 2 \pi n \), we take \( n = 0 \) without loss of generality in Eqs. (32), (35), and (36).
B. Equilibrium model

We first consider equilibrium solutions to Eqs. (32), (33), (35), and (36) in the absence of perturbations, i.e., $\delta A = 0$, $\delta^*_t = 0$, $\delta \theta^0 = 0$, and $\delta \theta^*_u = 0$. Consistent with the assumption that $\gamma^+_t$ is sufficiently large in comparison with $\gamma^+_u$, the zero-order orbit of an untrapped electron calculated from Eq. (33) can be approximated by

$$\theta^0 = \theta_u^0(0) + \beta^*_u c k^*_p t^*.$$  

(38)

Here, $\beta^*_u c = \text{const}$ is the average velocity of an untrapped electron in the ponderomotive frame. In Eq. (38), note that the modulation of the electron orbit by the ponderomotive potential has been neglected. Making use of Eq. (38) and the definition of the phase average in Eq. (34), it follows trivially that

$$\langle \sin(\theta^0 + \delta^*_t) \rangle_u = \langle \cos(\theta^0 + \delta^*_t) \rangle_u.$$  

(39)

That is, in Eqs. (35) and (36), the untrapped electrons do not contribute to any change in the equilibrium amplitude $\delta^*_t$ and phase $\delta^*_t$. Therefore, an appropriate quasisteady equilibrium state consistent with Eqs. (32), (35), and (36) is described by

$$\theta^0 = \theta^*_u(0) + \beta^*_u c k^*_p t^*,$$

and

$$\frac{\partial}{\partial t} \delta^*_t = 0,$$  

(41a)

$$\frac{\partial}{\partial z'} \delta^*_t = e^*_t c k^*_p.$$  

(41b)

Note from Eqs. (41) that $e^*_t < 1$ is required in the present analysis in order that the change in $\delta^*_t$ be small over the scale length of the ponderomotive potential ($A^* = 2\pi k^*_p z^*$). Making use of Eq. (28), the inequality $e^*_t < 1$ is equivalent to $(\Omega^*_p / \gamma^*_t c k^*_p)^2 > 2\Gamma^*_T$, where $\Gamma^*_T$ is the small parameter defined in Eq. (27).

To summarize, the equilibrium state is characterized by free-streaming untrapped electrons [Eq. (38)], trapped electrons with $\theta^0 + \delta^*_t = 0$ [Eq. (40a)], a primary electromagnetic wave with constant amplitude $\delta^*_t$ [Eq. (40)], and a slowly varying phase with $\delta^*_t = e^*_t c k^*_p$ [Eq. (41b)].

C. Linearization

We now linearize Eqs. (32), (33), (35), and (37) for small-amplitude perturbations about the equilibrium state described by Eqs. (38)–(41). In this regard, it is convenient to introduce the normalized amplitude perturbation $\Delta A$, defined by

$$\Delta A_s = \delta A_s / \delta^*_t.$$  

(42)

For $\theta^0 + \delta^*_t = 0$, it is straightforward to show that the small-amplitude perturbations $\Delta \theta_t^*$, $\Delta \theta_u^*$, $\Delta A_s$, and $\Delta_s$ evolve according to

$$\frac{d^2}{dt^2} \theta^0 + \omega_{tr}^2 (\theta^0 + \delta^*_t) = 0,$$

(43)

$$\frac{d^2}{dt^2} \Delta \theta^0 + \omega_{tr}^2 (\Delta A_s + \Delta_s) \Delta \theta^0$$

$$= -\Delta \theta^0 \text{Im} \left[ \left( \Delta A_s + i \delta^*_t \right) \exp(i \theta^0 + i \delta^*_t) \right],$$  

(44)

$$\left( \frac{\partial}{\partial t} + \frac{\partial}{\partial t} \right) \Delta A_s$$

$$= e^*_t c k^*_p \left( \Delta \theta^0 + \delta^*_t \right) + e^*_t c k^*_p \Delta \theta^0$$

$$\left( \frac{\partial}{\partial t} + \frac{\partial}{\partial t} \right) \delta^*_t + e^*_t c k^*_p \Delta A_s$$

$$= -e^*_t c k^*_p \left( \Delta \theta^0 + \delta^*_t \right) \sin(\theta^0 + \delta^*_t) \Delta \theta^0.$$  

(46)

In Eqs. (43)–(46) it should be kept in mind that $\Delta A_s(z^*,t^*)$ and $\Delta_s(z^*,t^*)$ are real-valued functions. In analyzing Eqs. (43)–(46) it is useful to express

$$\Delta \theta^0 = \Delta \psi \exp(i \theta^0 + i \delta^*_t) + \Delta \psi^* \exp(-i \theta^0 - i \delta^*_t),$$

(47)

where the complex amplitude $\Delta \psi = \Delta \psi^* + i \Delta \psi^*$ is slowly varying, and $\Delta \psi^*$ denotes the complex conjugate of $\Delta \psi$. Making use of Eqs. (44) and (47) and $\theta^*_u(0) + \beta^*_u c k^*_p t^*$, it is straightforward to show that $\Delta \psi$ evolves according to

$$\left( \frac{d^2}{dt^2} + 2i \beta^*_u c k^*_p \frac{d}{dt} + \left[ \omega_{tr}^2 \cos(\theta^0 + \delta^*_t) - \beta^*_u c^2 k^*_p \right] \right) \Delta \psi$$

$$= -\frac{1}{2i} \omega_{tr}^2 (\Delta A_s + i \delta^*_t).$$

(48)

For untrapped electron energy $\gamma^+_u$ sufficiently large compared to $1 + (a^*_u + \delta^*_t)^2$, it is valid to neglect $\omega_{tr}^2 \cos(\theta^0 + \delta^*_t)$ in comparison with $\beta^*_u c^2 k^*_p$ in Eq. (48). Therefore, Eq. (48) can be approximated by

$$\left( \frac{d^2}{dt^2} + 2i \beta^*_u c k^*_p \frac{d}{dt} - \beta^*_u c^2 k^*_p \right) (\Delta \psi^* + i \Delta \psi)$$

$$= -\frac{1}{2i} \omega_{tr}^2 (\Delta A_s + i \delta^*_t).$$

(49)

In Eq. (49), $\Delta \psi$, $\Delta \psi^*$, $\Delta A_s$, and $\Delta_s$ are all real quantities, and it follows that $\Delta \psi^* = \Delta \psi^* - i \Delta \psi^*$ evolves according to

$$\left( \frac{d^2}{dt^2} - 2i \beta^*_u c k^*_p \frac{d}{dt} - \beta^*_u c^2 k^*_p \right) (\Delta \psi^* - i \Delta \psi^*)$$

$$= \frac{1}{2i} \omega_{tr}^2 (\Delta A_s - i \delta^*_t).$$

(50)

Evidently, Eq. (49) [or Eq. (50)] describes the slow evolution of $\Delta \psi^*$ and $\Delta \psi^*$ in response to the amplifying wave perturbations $\Delta A_s$ and $\Delta_s$.

Substituting Eq. (47) into Eqs. (45) and (46), and making use of $\theta^*_u = \theta^*_u(0) + \beta^*_u c k^*_p t^*$ and the definition of the phase average in Eq. (34), it is straightforward to simplify the untrapped-electron contributions in the linearized wave equations. We readily obtain

$$\langle (\Delta \theta^0 + \delta^*_t) \cos(\theta^0 + \delta^*_t) \rangle_u$$

$$= (\Delta \theta^0 \cos(\theta^0 + \delta^*_t) \rangle_u = \Delta \psi^*,$$

(51)

$$\langle (\Delta \theta^0 + \delta^*_t) \sin(\theta^0 + \delta^*_t) \rangle_u$$

$$= (\Delta \theta^0 \sin(\theta^0 + \delta^*_t) \rangle_u = -\Delta \psi^*. $$

(52)
In Eqs. (51) and (52), the average of $\delta t$ times $\cos(\theta_0 + \delta \phi)$ or $\sin(\theta_0 + \delta \phi)$ vanishes because $\delta t$ is assumed to be slowly varying. Substituting Eqs. (51) and (52) into Eqs. (45) and (46), we obtain for the evolution of $\Delta \phi$, $\delta \phi$, and $\delta \psi$:

\[
\frac{\partial}{\partial t} + \frac{c^2k_z}{\omega} \frac{\partial}{\partial z} \Delta \phi = \epsilon_0 c k_z (\Delta \theta + \delta \phi) + \epsilon_0 c k_z \delta \psi,
\]

\[
\frac{\partial}{\partial t} + \frac{c^2k_z}{\omega} \frac{\partial}{\partial z} \delta \phi = -\epsilon_0 c k_z \Delta \phi + \epsilon_0 c k_z \delta \psi.
\]

To summarize, in the present analysis the final set of coupled, linearized equations for $\Delta \phi$, $\delta \phi$, $\delta \psi$, $\delta \Delta \phi$, and $\delta \delta \phi$ is given by Eqs. (43), (49), (50), (53), and (54).

**D. Dispersion relation in ponderomotive frame**

We now assume that the $t'$ and $z'$ dependence of the perturbations in Eqs. (43), (49), (50), (53), and (54) is proportional to

\[
\exp[-i(\Delta \omega t + z') + i(\Delta k z')],
\]

where Im$(\Delta \omega) > 0$ corresponds to instability (temporal growth). Consistent with neglecting beam dielectric effects in the dispersion relation (7), we also approximate $c^2k_z/\omega = c$ in Eqs. (53) and (54). The linearized equations (43), (49), (50), (53), (54) then become

\[
[(\Delta \omega)^2 - \delta \rho_{BG}] (\Delta \theta + \delta \phi) = (\Delta \omega)^2 \delta \phi,
\]

\[
-(\Delta \omega - \beta \epsilon c k_z)^2 (\delta \psi' + i \delta \psi'') = - \frac{(1/2i)\delta \rho_{BG}}{\delta \phi},
\]

\[
-(\Delta \omega + \beta \epsilon c k_z)^2 (\delta \psi' - i \delta \psi'') = \frac{(1/2i)\delta \rho_{BG}}{\delta \phi},
\]

\[
-i(\Delta \omega - \beta c k') \delta \Delta \phi = \epsilon_0 c k_z (\Delta \theta + \delta \phi) + \epsilon_0 c k_z \delta \psi,'
\]

\[
-i(\Delta \omega - \beta c k') \delta \delta \phi = -\epsilon_0 c k_z \Delta \phi + \epsilon_0 c k_z \delta \psi.'
\]

In Eqs. (57) and (58), it is useful to introduce the untrapped-electron susceptibilities $\chi^+$ and $\chi^-$ defined by

\[
\chi^+(\Delta k', \Delta \omega) = \frac{\delta \rho_{BG}}{(\Delta \omega + \beta \epsilon c k_z)^2} + \frac{\delta \rho_{BG}}{(\Delta \omega - \beta \epsilon c k_z)^2},
\]

\[
\chi^-(\Delta k', \Delta \omega) = \frac{\delta \rho_{BG}}{(\Delta \omega + \beta \epsilon c k_z)^2} - \frac{\delta \rho_{BG}}{(\Delta \omega - \beta \epsilon c k_z)^2}.
\]

From Eqs. (57) and (58) we readily obtain

\[
\delta \psi' = \frac{1}{2}(i \chi^- \delta \Delta \phi + \chi^+ \delta \delta \phi),
\]

\[
\delta \psi'' = \frac{1}{2}(- \chi^+ \delta \Delta \phi + \chi^- \delta \delta \phi),
\]

which express $\delta \psi'$ and $\delta \psi''$ directly in terms of the perturbed amplitude $\delta \Delta \phi$ and phase $\delta \delta \phi$. Solving Eq. (56) for $\Delta \theta + \delta \phi$ in terms of $\delta \phi$ and substituting Eqs. (63) and (64) into Eqs. (59) and (60) give two coupled homogeneous equations for $\delta \Delta \phi$ and $\delta \delta \phi$. Setting the resulting two-by-two determinant equal to zero, we obtain, after some straightforward algebraic manipulation,

\[
[(\Delta \omega' - c \Delta k') - i \epsilon_0 c k_z (\chi^+)^{-1}]^2
\]

\[
= (\epsilon_0 c k_z (\Delta \omega')^2 - [\Delta \omega')^2 - \delta \rho_{BG}] + i \epsilon_0 c k_z \chi^+)
\times (\epsilon_0 c k_z + i \epsilon_0 c k_z \chi^+).
\]

Equation (65) is the desired dispersion relation which relates the (complex) oscillation frequency $\omega'$ to the wave-number $k'$ and the system parameters $\epsilon_0$, $\epsilon_0 c k_z$, etc. Here, $\epsilon_0$, $\epsilon_0 c k_z$, $\chi^+$, and $\chi^-$ are defined in Eqs. (26), (61), and (62).

Before investigating detailed stability properties (Sec. IV), we show that the dispersion relation (65) reduces to familiar results in two limiting cases: (a) no untrapped electrons ($\delta \rho_{BG} = 0$), and (b) no trapped electrons ($\delta \rho_{BG} = 0$).

**No untrapped electrons ($\delta \rho_{BG} = 0$):** For $\delta \rho_{BG} = 0$, it follows from Eq. (26) that $\epsilon_0 c k_z = 0$, and Eq. (65) reduces to

\[
(\Delta \omega' - c \Delta k')^2 = \frac{\epsilon_0^2 c^2 k_z^2}{\Delta \omega')^2 - \delta \rho_{BG}'],
\]

which is the familiar dispersion relation (77,73) for the sideband instability assuming slowly varying equilibrium phase $\delta \rho_{BG}$ and no untrapped electrons. The detailed stability properties predicted by Eq. (67) are investigated in Ref. 37.

**No trapped electrons ($\delta \rho_{BG} = 0$):** For $\delta \rho_{BG} = 0$, it follows from Eq. (26) that $\epsilon_0 c k_z = 0$, and Eq. (65) can be expressed as

\[
0 = 1 - \frac{\delta \rho_{BG}^2}{(\Delta \omega')^2 - \delta \rho_{BG}'}.
\]

where use has been made of Eqs. (26) and (29). Consistent with assumption (b), we note that Eq. (69) is independent of the equilibrium wave amplitude $\delta \rho_{BG}$. When $\Delta \omega'$ and $\Delta k'$ are transformed back to the laboratory frame, it is straightforward to show that Eq. (69) is similar to the Compton-regime dispersion relation (77) obtained in the small-signal limit in the absence of trapped electrons.

We now return to the full dispersion relation in Eq. (65).

**Alternate form of the full dispersion relation:** It is useful to rewrite Eq. (65) in an alternate form which clearly delineates the trapped- and untrapped-electron contributions. Making use of Eqs. (61) and (62), rearranging terms in Eq. (65), and multiplying Eq. (65) by [(\Delta \omega')^2 - \delta \rho_{BG}']/(\Delta \omega')^2

\[
\times (\Delta \omega' - c \Delta k')^2,\]

it is straightforward to show that the dispersion relation can be expressed in the equivalent form
\[
1 - \frac{\hat{\omega}_{BT}^2}{(\Delta \omega')^2} - \frac{\epsilon_r^2 c^2 k_p^2}{(\Delta \omega' - c \hat{\Delta} k')^2} = \frac{1}{2} \epsilon_r c k_p \hat{\omega}_{BT} \left[ \frac{(\Delta \omega')^2 - \hat{\omega}_{BT}^2}{(\Delta \omega' - c \hat{\Delta} k')^2} \right]
\times \left[ \frac{1}{2} \epsilon_r c k_p \hat{\omega}_{BT} + 4 \Delta \omega' (\Delta \omega' - c \Delta k') \beta_v c k_p' + \epsilon_r c k_p' \left( (\Delta \omega')^2 + \beta_v c^2 k_p'^2 \right) \right] \left( 1 + \frac{(\Delta \omega')^2 - \hat{\omega}_{BT}^2}{\Delta \omega'} \right) \right].
\]

(70)

Here, \(\epsilon_r, \epsilon_r', \hat{\omega}_{BT},\) and \(\hat{\omega}_{BT}\) are defined in Eqs. (26) and (29). In the absence of untrapped electrons \((\epsilon_r' = 0)\), we note that Eq. (70) reduces directly to the familiar dispersion relation (67) for the sideband instability. That is, the effects of the untrapped electrons (the terms proportional to \(\epsilon_r'\)) are incorporated on the right-hand side of Eq. (70).

### IV. ANALYSIS OF DISPERSION RELATION

#### A. Dispersion relation in laboratory frame

We now transform the full dispersion relation (70) back to the laboratory frame. From Eq. (15), it follows that

\[
\Delta \omega' = \gamma_p (\Delta \omega - v_p \Delta k),
\]

\[
\Delta \omega' = \gamma_p \left[ (\Delta k - (v_p/c) \Delta \omega) \right],
\]

(71)

where \(\Delta \omega\) and \(\Delta k\) are the frequency and wavenumber of the perturbations in the laboratory frame. Making use of Eq. (71) and \(\gamma_p' = (1 - v_p/c)^{-1}\), it is straightforward to show that

\[
\Delta \omega' - c \Delta k' = \gamma_p' \left( 1 + \frac{v_p}{c} \right) \left( \Delta \omega - v_p \Delta k - ck_0 \frac{v_p}{c} \frac{\Delta k}{k_p}. \right)
\]

(72)

where \(k_p\) is defined in Eq. (18). We further introduce the shorthand notation

\[
\Delta \Omega = \Delta \omega - v_p \Delta k,
\]

\[
\Delta \Delta k = k_0(v_p/c) (\Delta k/k_p).
\]

(73a)

(73b)

Then, from Eqs. (71)–(73), \(\Delta \omega'\) and \(\Delta \omega' - c \Delta k'\) can be expressed in the equivalent form

\[
\Delta \omega' = \gamma_p \Delta \Omega,
\]

\[
\Delta \omega' - c \Delta k' = \gamma_p' \left( 1 + \frac{v_p}{c} \right) (\Delta \omega - c \Delta \Delta k).
\]

(74a)

(74b)

Equations (74) express \(\Delta \omega'\) and \(\Delta \omega' - c \Delta k'\) directly in terms of \(\Delta \Omega\) and \(\Delta \Delta k\), which are related to \(\Delta \omega\) and \(\Delta k\) in the laboratory frame by Eqs. (73).

To simplify the dispersion relation (70), it is convenient to introduce the dimensionless parameter

\[
\alpha_u = \left( \frac{\hat{\omega}_r'/\hat{\omega}_r'\gamma_p' / \hat{\omega}_r'}{\gamma_p' / \hat{\omega}_r'} \right)^3
\]

(75)

which is a measure of the ratio of the untrapped-electron density to the trapped-electron density, \(\hat{\rho}_r' / \hat{\omega}_r' = \hat{\rho}_u / \hat{\rho}_T\). Making use of Eqs. (16), (19), (25), (26), (28), (29), and (75), some straightforward algebra shows that \(\epsilon_r c k_p' \hat{\omega}_{BT}\) can be expressed in the equivalent forms

\[
\epsilon_r c k_p' \hat{\omega}_{BT} = 2 \Gamma \epsilon u c k_p' \left( \frac{\gamma_p' (\gamma_p' / \hat{\omega}_r')^3}{4 (1 + a_w^2)^{3/2}} \right) \left( 1 + v_p/c \right).
\]

(76)

and

\[
\epsilon_r c k_p' \hat{\omega}_{BT} = 2 \alpha_u \left( \Gamma \epsilon u c k_p' \gamma_p' \right) \left( 1 + v_p/c \right).
\]

(77)

Here, \(\Gamma\) is the (small) dimensionless gain parameter defined in Eq. (27), and the bounce frequency \(\Omega_B = (c^2 k_p' a_w \times \beta_v c^2 k_p'^2)^{1/2}\) of the deeply trapped electrons is defined in the laboratory frame in Eqs. (23) and (24). Finally, making use of Eq. (19), we note that \(\beta_v c k_p' = \gamma_p' (1 + v_p/c) \beta_v c k_0\). It is useful to define

\[
\hat{\beta}_v' = (1 + v_p/c) \beta_v'
\]

(78)

so that \(\beta_v' c k_p'\) can be expressed in the compact form

\[
\beta_v' c k_p' = \gamma_p' \hat{\beta}_v c k_0.
\]

(79)

After some algebraic manipulation that makes use of \(\hat{\Omega}_B = \hat{\omega}_{BT}/\gamma_p\) and Eqs. (74), (76), (77), and (79), it is straightforward to show that the dispersion relation (70) can be expressed in the equivalent form

\[
1 - \frac{\Omega_B^2}{(\Delta \Omega')^2} = \frac{4 \Omega_B^2}{(\Delta \Omega - c \Delta \Delta k)^2} \left[ \frac{\Omega_B^2}{(\Gamma \epsilon u c k_p')^3} \left( \frac{(\Delta \Omega')^2 - \Omega_B^2}{(\Delta \Omega - c \Delta \Delta k)^2} \right)^2 \right]
\times \left[ \left( \Omega_B \epsilon u c k_p' \right)^3 + 4 \frac{(\Delta \Omega')^2}{\Delta \Omega} \frac{\beta_v' c^2 k_0^2}{\Omega_B} \right]
\times \left( 1 + \frac{(\Delta \Omega')^2 - \Omega_B^2}{\Delta \Omega'} \right).
\]

(80)

Here, \(\alpha_u = \left( \frac{\hat{\omega}_r'/\hat{\omega}_r' \gamma_p' / \hat{\omega}_r'}{\gamma_p' / \hat{\omega}_r'} \right)^3\) [Eq. (75)], \(\Delta \Omega = \Delta \omega - v_p \Delta k\) [Eqs. (73)], \(\Delta \Delta k = k_0(v_p/c) \Delta k/k_p\) [Eqs. (73)], and \(\Gamma\) is the (small) dimensionless gain parameter defined in Eq. (27). For \(a_w \Delta \Delta k \ll 1\), making use of Eq. (27), we find that \(\Gamma\) can also be expressed in the more familiar form

\[
\Gamma = \frac{1}{4} \frac{a_w^2}{(1 + a_w^2)^{3/2}} \frac{4 \pi \hat{\omega}_r' c^2}{\gamma_p' \hat{\omega}_r' \gamma_p' c^2} \frac{1}{v_p/c} \ll 1
\]

(81)

where use has been made of \(\hat{\omega}_r' = \hat{\omega}_r' / \gamma_p\). Consistent with assumption (b) at the beginning of Sec. III, we require that \(\beta_v' c k_0\) be sufficiently large in comparison with \(\Omega_B\) in Eq. (80) in order that the untrapped-electron motion be only weakly modulated by the ponderomotive potential.

Equation (80) constitutes the final dispersion relation analyzed numerically in Sec. IV B. For \(\alpha_u = 0\), which corresponds to no untrapped electrons (\(\hat{\rho}_u = 0\)), Eq. (80) is the familiar dispersion relation37,71 for the sideband instability in circumstances where the equilibrium wave phase is slowly varying (Eq. (41)). For \(\alpha_u \neq 0\), however, it is found that the untrapped electrons can significantly modify stability behavior (Sec. IV B).
B. Numerical results

In analyzing the dispersion relation (80) it is sensible to introduce the total density of beam electrons \( \hat{n}_b = \hat{n}_T + \hat{n}_u \).

We define the fraction of beam electrons that are untrapped \( f_u \) and the fraction of beam electrons that are trapped \( f_T \) by

\[
 f_u = \frac{\hat{n}_u}{\hat{n}_b}, \quad f_T = \frac{\hat{n}_T}{\hat{n}_b} = 1 - f_u. \tag{82}
\]

(Keep in mind that \( \hat{n}_u' = \frac{\hat{n}_u}{\gamma_p}, \hat{n}_T' = \frac{\hat{n}_T}{\gamma_p}, \) and \( \hat{n}_b' = \frac{\hat{n}_b}{\gamma_p} \) are the densities in the ponderomotive frame. Therefore, \( f_u \) and \( f_T \) are also given by \( f_u = \hat{n}_u' / \hat{n}_b' \) and \( f_T = \hat{n}_T' / \hat{n}_b' \).) We further define the gain factor \( \Gamma_b \) associated with the total beam density by

\[
 \Gamma_b^3 = (\hat{n}_b / \hat{n}_T) \Gamma_T^3, \tag{83}
\]

where \( \Gamma_T^4 \) is defined in Eq. (81). Because \( (\gamma_T' / \gamma_b')^3 \approx 1 \) for \( a_b' / \gamma_b'^2 \ll 1 \), it follows from Eq. (75) that \( \alpha_u = \hat{n}_u' / \hat{n}_T' = \hat{n}_u / \hat{n}_T \) is an excellent approximation. Therefore, from Eqs. (82) and (83), \( \alpha_u \Gamma_b^3 \) and \( \Gamma_T^3 \) can be expressed in terms of \( \Gamma_b^3 \) and \( f_u \) by

\[
 \alpha_u \Gamma_b^3 = f_u \Gamma_b^3, \quad \Gamma_T^3 = (1 - f_u) \Gamma_b^3, \tag{84}
\]

where \( f_u = \hat{n}_u / \hat{n}_b \) is the fraction of beam electrons that are untrapped.

In the numerical analysis of Eq. (80), we normalize all frequencies to \( \Gamma_b c k_0 \) and introduce the dimensionless parameters

\[
\bar{\Omega}_B = \Delta \bar{\Omega} / \Gamma_b c k_0, \quad \bar{K} = c \Delta K / \Gamma_b c k_0, \quad \Delta \bar{\Omega} = \Delta \bar{\Omega} / \Gamma_b c k_0, \quad \bar{K} = c \Delta K / \Gamma_b c k_0. \tag{85}\]

In Eqs. (85) note that \( \bar{\Omega}_B = \Omega_B / \Gamma_b c k_0 \) is a dimensionless measure of the pump strength (amplitude of the primary electromagnetic wave). In Eqs. (85) we have normalized all quantities to \( \Gamma_b c k_0 \), which (within a constant factor) is the usual FEL growth rate for a cold, unbunched, electron beam with density \( \hat{n}_b \). Alternatively, quantities could have been normalized to the synchrotron frequency \( \Omega_B \). The latter normalization, however, would be less satisfactory because we wish to investigate detailed stability properties over a wide range of \( \Omega_B \) and \( f_u \) (with \( \hat{n}_b \) fixed). Substituting Eqs. (84) and (85) into Eq. (80), we find that the dispersion relation can be expressed in the equivalent form

\[
1 = \frac{\bar{\Omega}_B^2}{(\Delta \bar{\Omega})^2} \frac{4(1 - f_u)}{(\Delta \bar{\Omega} - \Delta \bar{K})^2}
\times \left[ f_u + 4(\Delta \bar{\Omega})(\Delta \bar{\Omega} - \Delta \bar{K})\bar{\beta}_u + \frac{2(1 - f_u)}{\bar{\Omega}_B^2} \left( \Delta \bar{\Omega}^2 + \bar{\beta}_u^2 \right) \left( 1 + \frac{(\Delta \bar{\Omega})^2}{(\Delta \bar{\Omega})^2 - \bar{\Omega}_B^2} \right) \right]. \tag{86}
\]

The dispersion relation (86) has been solved numerically for the normalized growth rate \( \text{Im}(\Delta \bar{\Omega}) \).
\[ \text{Im}(\Delta \Omega) / \Gamma_e c k_0 \text{ and the normalized real frequency} \]
\[ \text{Re}(\Delta \Omega) = \text{Re}(\Delta \Omega) / \Gamma_e c k_0 \text{ versus the normalized wavenumber} \Delta K = \Delta K / \Gamma_e k_0 \text{ over a wide range of system parameters} \]
\[ \Omega_B = \Omega_B / \Gamma_e c k_0 \text{ and} \hat{\beta}_u = \hat{\beta}_u / \Gamma_e. \]

Typical results are illustrated in Figs. 3–8 for a fixed value of \( \hat{\beta}_u = 3 \times 2^{1/3} \approx 4.3267 \), and normalized pump strength ranging from \( \Omega_p / \Gamma_e c k_0 = 2^{1/3} \approx 1.2599 \) (Figs. 3–5), to \( \Omega_p / \Gamma_e c k_0 = 0.5 \) (Fig. 6), to \( \Omega_p / \Gamma_e c k_0 = 0.2 \) (Figs. 7 and 8).

In Fig. 3, we illustrate typical numerical results and establish the sign conventions inherent in the dispersion relation (86). In particular, for \( \Omega_B / \Gamma_e c k_0 = 2^{1/3} \) and \( \hat{\beta}_u = \hat{\beta}_u / \Gamma_e = 0.5 \), Fig. 3 shows plots of the normalized growth rate \( \text{Im}(\Delta \Omega) / \Gamma_e c k_0 \) and real oscillation frequency \( \text{Re}(\Delta \Omega) / \Gamma_e c k_0 \) versus normalized wavenumber \( \Delta K / \Gamma_e k_0 \) obtained from Eq. (86) for the two classes of unstable solutions. The results in Figs. 3(a) and 3(b) pertain to the unstable mode driven by the \textit{untrapped} electrons, whereas the results in Figs. 3(c) and 3(d) pertain to the unstable mode driven by the \textit{trapped} electrons. For \( \hat{\beta}_u = \hat{\beta}_u / \Gamma_e = 0.5 \), both classes of unstable modes are of course affected by the other population of electrons. With regard to the symmetries inherent in Eq. (86) and evident in Fig. 3, we note that

\[ \text{Re} \Delta \Omega( - \Delta K) = - \text{Re} \Delta \Omega( \Delta K), \]
\[ \text{Im} \Delta \Omega( - \Delta K) = \text{Im} \Delta \Omega( \Delta K), \] (87)

are (necessarily) satisfied by both classes of unstable modes. Equation (87) assures that the Fourier transform functions for the perturbed quantities \( \delta A, \delta \phi, \delta \theta, \) etc., correspond to transforms of \textit{real-valued} functions. The roots of Eq. (86) corresponding to the trapped-electron mode and the untrapped-electron mode are distinguished by tracking both \( \text{Re} \Delta \Omega \) and \( \text{Im} \Delta \Omega \) for the two modes; the real frequency shifts for these two modes are clearly separated, as is evident from Figs. 3(b) and 3(d). For simplicity of notation, keep-
FIG. 5. Plots of the normalized real frequency $\text{Re}(\Delta \Omega)/\Gamma_b c k_0$ vs $\Delta K / \Gamma_b k_0$ obtained from Eq. (86) for $\Omega_b / \Gamma_b c k_0 = 2^{1/3}$, $\beta_b = 3 \times 2^{1/3}$, and (a) $f_u = 0$, (b) $f_u = 0.5$, and (c) $f_u = 1$.

FIG. 6. Plots of $\text{Im}(\Delta \Omega)/\Gamma_b c k_0$ vs $\Delta K / \Gamma_b k_0$ obtained from Eq. (86) for $\Omega_b / \Gamma_b c k_0 = 0.5$, $\beta_b = 3 \times 2^{1/3}$, and (a) $f_u = 0$, (b) $f_u = 0.2$, (c) $f_u = 0.5$, (d) $f_u = 0.8$, and (e) $f_u = 1$. 

R. C. Davidson and J. S. Wurtele 2835
ing in mind the symmetries in Eq. (77) and Fig. 3, throughout the remainder of this paper we display only the stability results corresponding to the rightmost growth curves in Figs. 3(a) and 3(c). That is, in Figs. 4–8, the stability results are presented only for the rightmost lobes of the growth rate curves. With populations of both trapped and untrapped electrons, it is found that the untrapped-electron mode corresponding to the rightmost lobe in Fig. 3(a) can exhibit growth for negative as well as positive values of \( \Delta K \). This effect is most pronounced at small values of \( \Omega / \Gamma_b c k_0 \) (see Figs. 6 and 7).

Figure 4 shows plots of the normalized growth rate \( \text{Im}(\Delta \Omega)/\Gamma_b c k_0 \) vs \( \Delta K/\Gamma_b k_0 \) obtained from Eq. (86) for \( \Omega_b / \Gamma_b c k_0 = 2^{1/3} \) and fraction of untrapped electrons ranging from \( f_u = 0 \) [Fig. 4(a)] to \( f_u = 1 \) [Fig. 4(e)]. For \( f_u = 0 \), Fig. 4(a) corresponds to the familiar growth rate curve [3,73] for the sideband instability assuming a slowly varying equilibrium wave phase and that all of the electrons are deeply trapped. [Indeed, for \( f_u = 0 \) and \( \Omega_b = 2^{1/3} \), Eq. (68) can be solved analytically, [3] which gives a useful calibration of the numerical results.] Adding an untrapped electron component, it is evident from Figs. 4(b)–4(e) that a new unstable mode (driven by the untrapped electrons) is introduced. The untrapped-electron mode is represented by the dotted curves in Figs. 4(b)–4(e), whereas the sideband mode is represented by the solid curves. As expected for zero energy spread, the untrapped-electron mode in Figs. 4(b)–4(e) has a relatively broad bandwidth in \( \Delta K \) space. Moreover, as \( f_u \) is increased (thereby decreasing the fraction of trapped electrons), the growth rate and bandwidth of the sideband instability continue to decrease as \( f_u \) is increased from \( f_u = 0.2 \) [Fig. 4(b)], to \( f_u = 0.5 \) [Fig. 4(c)], to \( f_u = 0.8 \) [Fig. 4(d)]. Indeed, for \( f_u = 1 \) (no trapped electrons), the sideband instability is completely absent (as expected), and only the instability driven by the untrapped electrons is present [Fig. 4(e)].

It is evident from Figs. 4(a)–4(e) that the properties of \( \text{Im}(\Delta \Omega)/\Gamma_b c k_0 \) vs \( \Delta K/\Gamma_b k_0 \) differ in detail for the two unstable modes. However, an equally striking feature of Fig. 4 is that the characteristic maximum growth rate of the most unstable mode varies by only a small amount (less than 25%) between the case where there are no untrapped electrons \( f_u = 0 \) in Fig. 4(a)] to the case where there are no trapped electrons \( f_u = 1 \) in Fig. 4(e)]. The present analysis suggests that the linear and nonlinear evolution of the beam electrons and radiation field may be substantially modified by the presence of an untrapped-electron component when \( f_u \geq 0.2 \).

Figure 5 shows plots of the normalized real frequency \( \text{Re}(\Delta \Omega)/\Gamma_b c k_0 \) vs \( \Delta K/\Gamma_b k_0 \) obtained from Eq. (86) for \( \Omega_b / \Gamma_b c k_0 = 2^{1/3} \) and \( f_u = 0 \) [Fig. 5(a)], \( f_u = 0.5 \) [Fig. 5(b)], and \( f_u = 1 \) [Fig. 5(c)]. The system parameters in Figs. 5(a), 5(b), and 5(c) are identical to Figs. 4(a), 5(c), and 5(e), respectively. Moreover, \( \text{Re}(\Delta \Omega) \) is plotted only
over the unstable range of $\Delta K$, and the solid curves in Fig. 5 correspond to the sideband mode whereas the dotted curves correspond to the untrapped-electron mode. Evidently, $\text{Re}(\Delta \Omega)$ increases monotonically with $\Delta K$ for the sideband mode [Figs. 5(a) and 5(b)]. Furthermore, the magnitude of $\text{Re}(\Delta \Omega)$ is somewhat larger for the untrapped-electron mode [Figs. 5(b) and 5(c)]. Moreover, $\text{Re}(\Delta \Omega)$ is approximately constant for the untrapped-electron mode for $\Delta K/T_b k_0 \geq 5$.

In Fig. 6, the normalized pump strength is reduced to $\Omega_p/\Gamma_b k_0 = 0.5$. In particular, Fig. 6 shows plots of the normalized growth rate $\text{Im}(\Delta \Omega)/\Gamma_b k_0$ vs $\Delta K/T_b k_0$ obtained from Eq. (86) for $\Omega_p/\Gamma_b k_0 = 0.5$ and fraction of untrapped electrons ranging from $f_u = 0$ [Fig. 6(a)] to $f_u = 1$ [Fig. 6(e)]. In Fig. 6, the general features of the growth rate curves for the sideband mode (solid curves) and the untrapped-electron mode (dotted curves) are qualitatively similar to those of Fig. 4, although the bandwidth of the sideband instability is considerably larger for the smaller value of $\Omega_p/\Gamma_b k_0$ chosen in Fig. 6 [compare Figs. 4(a) and 6(a)]. Moreover, the maximum growth rate of the untrapped-electron mode shifts from negative values of $\Delta K$ for $f_u \leq 0.5$ [Figs. 6(b) and 6(c)] to positive values of $\Delta K$ for $f_u > 0.5$ [Figs. 6(d) and 6(e)]. As in Fig. 4, it is evident from Fig. 6 that the characteristic maximum growth rate of the most unstable mode varies by only a small amount over the entire range from $f_u = 0$ [Fig. 6(a)] to $f_u = 1$ [Fig. 6(e)]. However, the detailed properties of $\text{Im}(\Delta \Omega)/\Gamma_b k_0$ vs $\Delta K/T_b k_0$ differ considerably for the two modes.

Finally, in Figs. 7 and 8, the normalized pump strength is reduced further to $\Omega_p/\Gamma_b k_0 = 0.2$. Shown are plots of $\text{Im}(\Delta \Omega)/\Gamma_b k_0$ (Fig. 7) and $\text{Re}(\Delta \Omega)/\Gamma_b k_0$ (Fig. 8) vs $\Delta K/T_b k_0$ obtained from Eq. (86) for $\Omega_p/\Gamma_b k_0 = 0.2$ and values of $f_u$ ranging from $f_u = 0$ to $f_u = 1$. As in Figs. 4 and 6, only the sideband mode is unstable for $f_u = 0$ [Fig. 7(a)], whereas only the untrapped-electron mode is unstable for $f_u = 1$ [Fig. 7(e)]. Finally, in Figs. 4 and 6, the characteristic maximum growth rate of the most unstable mode varies by only a small amount over the entire range of $f_u$ considered in Fig. 7.

V. CONCLUSIONS

This paper has investigated the detailed influence of untrapped electrons on the sideband instability in a helical wigglar free electron laser. Small-amplitude perturbations are assumed about a constant-amplitude ($\delta_0 = \text{const}$) primary electromagnetic wave with a slowly varying equilibrium phase $\phi^0$ [Eqs. (40) and (41)]. A simple model is adopted in which all of the trapped electrons are deeply trapped, and the equilibrium motion of the untrapped electrons (assumed monoenergetic) is only weakly modulated by the ponderomotive potential. The theoretical model is based on the single-particle orbit equations together with Maxwell’s equations and appropriate statistical averages (Sec. II). Like our recent treatment of the sideband instability (which neglects the effects of untrapped electrons), the present analysis is carried out in the ponderomotive frame, which leads to a substantial simplification in deriving the dispersion relation (70) (Sec. III). Transforming Eq. (70) back to the laboratory-frame frequency $\omega = \omega_0 + \Delta \omega$ and wavenumber $k = k_0 + \Delta k$, detailed properties of the sideband instability are investigated, including the effects of the untrapped electrons (Sec. IV).

The resulting dispersion relation (86) has been analyzed numerically over a wide range of the dimensionless pump strength $\Omega_p/\Gamma_b k_0$ and the fraction of untrapped electrons $f_u = \bar{n}_u/\bar{n}_b$. To summarize briefly, when both trapped and untrapped electrons are present, there are generally two types of unstable modes, which we refer to as the sideband mode, and the untrapped-electron mode. For $f_u = 0$, only the sideband instability is present (as expected). As $f_u$ is increased, the growth rate of the sideband instability decreases, whereas the growth rate of the untrapped-electron mode increases until only the untrapped-electron mode is unstable for $f_u = 1$ (Figs. 4, 6, and 7).

It is evident from the present analysis that the detailed growth properties are quite different for the two unstable modes. However, a very important feature of the stability results is that the characteristic maximum growth rate of the
most unstable mode varies by only a small amount over the entire range of \( f'_s \) from \( f'_s = 0 \) (no untrapped electrons) to \( f'_s = 1 \) (no trapped electrons). The present analysis suggests that the linear and nonlinear evolution of the beam electrons and radiation field may be substantially modified by the presence of an untrapped-electron component when \( f'_s \gtrsim 0.2 \).
